Mullite has had significant applications in refractories and pottery for millennia and new applications in structures, electronics, and optics are the focus of active research. Richard Bradt of the University of Alabama, Tuscaloosa, provides Chap. 3, a focused discussion of the intriguing minerals (andalusite, kyanite, and sillimanite) that do not appear on the common alumina-silica phase diagram as they are formed at high geological pressures and temperatures. Nonetheless, these minerals with a one-to-one ratio of alumina to silica are widely found in nature and are used in numerous applications. Mullite or porcelainite is a rare silicate mineral of post-clay genesis. It can form two stoichiometric forms: $3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$ or $2\text{Al}_2\text{O}_3 \cdot \text{SiO}_2$. Unusually, mullite has no charge balancing cations present. As a result, there are three different aluminium sites: two distorted tetrahedral and one octahedral. Mullite was first described in 1924 for an occurrence on the Isle of Mull, Scotland. It occurs as argillaceous inclusions in volcanic rocks in the Isle of Mull, inclusions in sillimanite within a tonalite. Mullite ceramics with controlled microstructure in terms of grain size/shape, pore and glassy phase content were produced from sol-derived pastes using extrusion. Particular attention has been given to the development of a continuous process which is suitable for the preparation of high-solids-loading mullite pastes from two different starting mullite precursors, namely, diphasic and molecular mixed mullite sols. A combined processing technique comprising vacuum filtering and pressure filtration was introduced in order to obtain extrudable mullite pastes from low solids-loading colloidal sols.

sillimanite within a tonalite Besides its importance for conventional ceramics, mullite has become a choice of material for advanced
structural and functional ceramics due to its favourable properties. Some outstanding properties of mullite are low thermal expansion,
low thermal conductivity, excellent creep resistance, high-temperature strength, and good chemical stability. The mechanism of mullite
formation depends upon the method of combining the alumina- and silica-containing reactants. It is also related to the temperature at
which the reaction leads to the formation of mullite (mullitisation temperature). Mullitisation
